

# rarray: Multidimensional Runtime Arrays for C++

Ramses van Zon

January 4, 2015

## 1 For the impatient: the what, why and how of rarray

### What:

Rarray provides multidimensional arrays with dimensions determined at runtime.

### What not:

No linear algebra, overloaded operators etc.

### Why:

Usually faster than alternatives,

Uses the same accessors as compile-time (automatic) arrays,

Data is guaranteed to be contiguous for easy interfacing with libraries.

### How:

The header file `rarray.h` provides the type `rarray<T,R>`, where `T` is any type and `R` is the rank. Element access uses repeated square brackets. Copying rarrays or passing them to functions mean shallow copies, unless explicitly asking for a deep copy.

Define a $n \times m \times k$ array of floats:	<code>rarray&lt;float,3&gt; b(n,m,k);</code>
Define a $n \times m \times k$ array of floats with data already allocated at a pointer <code>ptr</code> :	<code>rarray&lt;float,3&gt; c(ptr,n,m,k);</code>
Element <code>i,j,k</code> of the array <code>b</code> :	<code>b[i][j][k]</code>
Pointer to the contiguous data in <code>b</code> :	<code>b.data()</code>
Extent in the <code>i</code> th dimension in <code>b</code> :	<code>b.extent(i)</code>
Shallow copy of the array:	<code>rarray&lt;float,3&gt; d=b;</code>
Deep copy of the array:	<code>rarray&lt;float,3&gt; e=b.copy();</code>
A rarray using an existing automatic array:	<code>float f[10][20][8]={...}; rarray&lt;float,3&gt; g=RARRAY(f);</code>
A rarray copy of an existing automatic array:	<code>rarray&lt;float,3&gt; h=RARRAY(f).copy();</code>
Output a rarray to screen:	<code>std::cout &lt;&lt; h &lt;&lt; endl;</code>
Read a rarray from keyboard:	<code>std::cin &gt;&gt; h;</code>

## 2 Introduction

While C and thus C++ has some support for multidimensional arrays whose sizes are known at compile time, the support for arrays with sizes that are known only at runtime, is limited. For one-dimensional arrays, C++ has a reasonable allocation construction in the operators `new` and `delete`. An example of the standard way to allocate a one-dimensional array is the following piece of code:

```
float* a;
int n = 1000;
a = new float[n];
a[40] = 2.4;
delete[] a;
```

It is important to note that this code also works if `n` was not known yet, e.g., if it was passed as a function argument or read in as input.

In the above code snippet, the `new/delete` construct assigns the address of the array to a pointer. This pointer does not remember its size, so this is not really an 'array'. The standard C++ library does provide a one-dimensional array that remembers its size in the form of the `std::vector`, e.g.

```
std::vector a;
int n = 1000;
a.reserve(n);
a[40] = 2.4;
a.clear();
```

Multi-dimensional runtime-allocated arrays are not supported by C++. The textbook C++ solution for multidimensional arrays that are dynamically allocated during runtime, is as follows:

```
float*** a;
a = new float**[dim0];
for (int i=0;i<dim0;i++) {
    a[i] = new float*[dim1];
    for (int j=0;j<dim1;j++)
        a[i][j] = new float[dim2];
}
```

Drawbacks of this solution are the non-contiguous buffer for the elements (so it's unusable for many libraries) and having to keep track of array dimensions. At first, there seems to be no shortage of libraries to fill this lack of C++ support for dynamic multi-dimensional arrays, such as

- Blitz++;
- The Boost Multidimensional Array Library (`boost::multiarray`);

- Eigen;
- Armadillo; and
- Nested vectors from the Standard Template Library.

These typically do have some runtime overhead compared to the above textbook solution, or do not allow arbitrary ranks. In contrast, the purpose of the rarray library is to be a minimal interface for runtime multidimensional arrays with *minimal to no performance overhead* compared to the textbook solution.

**Example:**

```
#include "rarray.h"
int main()
{
    rarray<float,3> a(256, 256, 256);
    a[1][2][3] = 105;
}
```

**Design Points**

1. To have dynamically allocated multidimensional arrays that combine the convenience of automatic c++ arrays with that of the typical textbook dynamically allocated pointer-to-pointer structure.

The compatibility requirement with pointer-to-pointer structures is achieved by allocating a pointer-to-pointer structure. This accounts for most of the memory overhead of using rarray.

2. To be as fast as pointer-to-pointer structures.
3. To have rarrays know their sizes, so that can be passed to functions as a single argument.
4. To enable interplay with libraries such as BLAS and LAPACK: this is achieved by guaranteeing contiguous elements in the multi-dimensional array, and a way to get this data out.

Relatedly, it should be allowed to use an existing buffer.

The guarantee of contiguity means strided arrays are not supported.

5. To optionally allow bounds checking.
6. To avoid cluttered semantics around const when converting to pointer-to-pointer structures.

**Features of rarray:**

- Can use any data type T and any rank R.
- Views on existing contiguous arrays.
- Does shallow copies by default, but also has a deep copy method.
- Elements are accessible using repeated square brackets, like C/C++ arrays.
- Can be emptied with the `clear` method.
- Can be filled with a uniform value with the `fill` method.

- Can be reshaped.
- Automatic C-style arrays can be converted to rarrays using `RARRAY`.
- Checks index bounds if the preprocessor constant `RA_BOUNDSCHECK` is defined.
- A method `is_clear` to check if the rarray is uninitialized.
- A method to get the number of elements in each dimension (`extent`), or in all dimensions (`shape`).
- A method to obtain the total number of elements in the array (`size`).
- A method to make the data type of the array `const` (`const_ref`).
- Conversion methods using the member function `data()` for conversions to a `T*` or `const T*`, using the method `ptr_array()` for conversions to `T*const*` or `const T*const*`, and using the method `noconst_ptr_array()` for the conversion to a `T**`.
- Streaming input and output.

## 3 Using the rarrays

### 3.1 Defining a multidimensional rarray

To use `rarray`, first include the header file `rarray.h`:

```
#include "rarray.h"
```

This defines the (template) classes `rarray<T,R>`, where `T` is the element type, and `R` is the rank (a positive integer). Instances can now be declared as follows:

```
rarray<float,3> s(256,256,256);  
s[1][2][3] = 105;  
// do whatever you need with s
```

or, using an external, already allocated buffer, as

```
float* data=new float[256*256*256];  
rarray<float,3> s(data,256,256,256);  
s[1][2][3] = 105;  
// do whatever you need with s  
delete[] data;
```

Without the `delete[]` statement in the latter example, there would be a memory leak. This reflects that `rarray` is in this case not responsible for the content. The data pointer can also be retrieved using `s.data()`.

Even in the former case (`rarray<float,3> s(256,256,256)`), one can release the memory of this array by calling `s.clear()` before the `rarray` goes out of scope.

The construction specifying a number of extents as arguments works for arrays with rank up to and including 11. For arrays with larger rank, you have to pass an pointer to the array of extents.

### 3.2 Accessing the elements

The elements of rarray objects are accessed using the repeated square bracket notation as for automatic C++ arrays (by design). Thus, if `s` is a rarray of rank `R`, the elements are accessed using `R` times an index of the form `[ni]`, i.e. `s[n0][n1] . . . [nR-1]`. For example:

```
for (int i=0;i<s.extent(0);i++)
  for (int j=0;j<s.extent(1);j++)
    for (int k=0;k<s.extent(2);k++)
      s[i][j][k] = i+j+k;
```

### 3.3 Streaming input and output

Although it is usually preferable to store large arrays in binary, rarray does provide streaming operators `<<` and `>>` to read and write to standard C++ iostreams. The output produced by the output streaming operator is like that of automatic arrays initializers: Each dimension is started and ended by `{` and `}` and components are comma separated. E.g.:

```
int buf[6] = {1,2,3,4,5,6};
rarray<int,2> arr(buf,3,2)
std::cout << arr;
```

will print `{{1,2},{3,4},{5,6}}`. The streaming operators use those of the element types.

Reading would not be unambiguous for some types, e.g. for `std::string`, that can contain the syntactic elements `{`, `}`, `,`, or `#`. If these elements are found in the output of an element, the element is prepended with a string that encodes the string length of the output. This prepending string starts with a `#` character, then the length of the string output for the element (excluding the prepended part), followed by a `:` character.

The input stream operators expect the same format as input.

### 3.4 Copying and function arguments

In C++, when we copy a variable of a built-in type to a new variable, the new copy is completely independent of the old variable. Likewise, the default way of passing arguments to a function involves a complete copy for built-in types. For C-style arrays, however, only the pointer to the first element gets copied, not the whole array. The latter is called a shallow copy. Rarrays use shallow copies much like pointers, with the additional functionality that memory allocated by the rarray gets released.

What does this essentially mean? Well:

1. You can pass rarrays by value to function, which is as if you were passing a pointer.
2. When you assign one rarray to another, the other simply points to the old one.
3. If you wish to do a deep copy, i.e., create a new array independent of the old array, you need to use the copy method.

### 3.5 Reshaping the rarray

To use the data in an rarray but access it in a different ‘shape’, one can

1. create a new rarray which uses the data from the first rarray. E.g.

```
void dump(const rarray<double,3>& r) {
    rarray<double,1> rflat(r.data(), r.size());
    for (int i=0;i<r.size();i++)
        std::cout << rflat[i] << ' ';
    std::cout << std::endl;
}
```

2. or one can reshape the existing rarray with the desired dimensions. E.g.

```
void dump(rarray<double,3> r) {
    r.reshape(r.data(), 1, 1, r.size());
    for (int i=0;i<r.size();i++)
        std::cout << rflat[0][0][i] << ' ';
    std::cout << std::endl;
}
```

This only works if the new and old shape have the same ranks.

The last example has no side effects, i.e., the original rarray that was passed to the dump function retains its shape.

Note that in both methods, the total size of the new shape should be less or equal to that of the old shape, because no additional data is allocated by the reshape method.

There is an important restriction to using reshape, namely, that only shallow copies of rarrays can be reshaped with the reshape method. Original rarrays cannot. Because in the above example, r is an argument, it is a shallow copy of the array, and can be reshaped. If the argument were of reference type (e.g. rarray<double,3>& r), then the reshape would not be allowed. The reason for this is that reshaping an original array would make any existing shallow copies invalid. Once reshaped, the rarray is now an original rarray, and cannot be reshaped again.

This can be frustratingly annoying in context where you want to reshape an original array when no shallow copies exist. You can force reshape to do its work by given an additional argument ‘RA\_FORCE’ as the last argument to ‘reshape’. This should only be used when no shallow copies exist.

### 3.6 Optional bounds checking

If the preprocessor constant RA\_BOUNDSCHECK is defined, an out\_of\_bounds exception is thrown if

- an index is too small or too large;
- the size of dimension is requested that does not exist (in a call to extent(int i));
- a constructor is called with a zero pointer for the buffer or for the dimensions array;

- a constructor is called with too few or too many arguments (for  $R \leq 11$ ).

RA\_BOUNDSCHECK can be defined by adding the `-DRA_BOUNDSCHECK` argument to the compilation command, or by `#define RA_BOUNDSCHECK` before the `#include "rarray.h"` in the source.

## 4 Comparison with standard alternatives

The more-or-less equivalent automatic array version

```
float arr[256][256][256];
arr[1][2][3] = 105;
```

is a little simpler, but automatic arrays are allocated on the stack, which is typically of limited size. Another drawback is that this array cannot be passed to functions that do not hard-code exactly matching dimensions except for the last one.

Using `rarray` also has benefits over another common C++ solution using the STL:

```
#include <vector>
int main() {
    using std::vector;
    int n = 256;                // size per dimension
    vector<vector<vector<float>>> v(n); // allocate for top dimension
    for (int i=0; i<n; i++) {
        v[i].reserve(n);        // allocate vectors for middle dimension
        for (int j=0; j<n; j++)
            v[i][j].reserve(n); // allocate elements in last dimension
    }
    v[1][2][3] = 105;           // assign to element (for example)
}
```

which is complicated, is non-contiguous in memory, and likely slower.

## 5 Class definition

### 5.1 Interface

Effectively, the interface part of a `rarray` object is defined as follows:

```
template<typename T, int R>
class rarray {
public:
    rarray();                // create uninitialized array
    rarray(int extent0, ...); // constructor for  $R \leq 11$ 
```

```

rarray(const int* extents);           // alternative: extents in array
rarray(T* data, int extent0, ...);    // construct with existing data
rarray(T* data, const int* extents);  // alternative: extents in array
rarray(const rarray<T,R> &a);         // shallow copy constructor
~rarray();                           // destructor
void reshape(int extent0, ..., RAbol); // change shape (not data)
void reshape(const int* extent, RAbol); // change shape (not data)
void clear();                         // release memory
void fill(const T& value);            // fill with uniform value
bool is_clear() const;               // check if uninitialized;
rarray<T,R> copy() const;             // deep copy
const int* shape() const;            // all extents as C-style array
int extent(int i) const;             // extent in dimension i
int size() const;                   // total number of elements
T* data() const;                   // start of internal buffer
T*const*... ptr_array() const;       // convert to a T*const*...
T**... noconst_ptr_array() const;    // converts to a T**...
rarray<const T,R>& const_ref() const; // convert to const elements
rarray<T,R>& operator=(const rarray<T,R> &a); // shallow assignment
rarray<const T,R-1> operator[](int i) const; // element access
rarray<T,R-1> operator[](int i);       // element access
};

```

## 5.2 Methods

**Definition:** `int extent(int i) const;`

This method returns the size of dimension `i`.

**Definition:** `const int* shape() const;`

This method returns the size of all dimensions as a c array.

**Definition:** `int size() const;`

This method returns the total number of elements.

**Definition:** `T* data() const;`

This method returns a pointer to a `T*`. Const-correct.

**Definition:** `T*const*... ptr_array() const;`

This method returns a pointer to a `T*const*...`. Const-correct.

**Definition:** `T**... noconst_ptr_array() const;`

This method returns a pointer to a `T**...`. This conversion breaks const-correctness.

**Definition:** `rarray<const T,R>& const_ref() const;`

This method creates reference to this with const elements.

**Definition:** `void reshape(int extent0, ..., RAbol force=RAbol(false));`

This method can be used to change the shape of the rarray. The data in the underlying

buffer will not change. Note that the number of dimensions must remain the same and the total new size must be less or equal to the old size. This works only for arrays with rank up to and including 11. Warning: if the rarray is not a shallow copy of another rarray, the resizing will not be performed, to protect any existing shallow copies. If no such copies exist, one can give 'RA\_FORCE' as the last (optional) argument to reshape an 'original' array.

**Definition:** `void reshape(const int* extents, RAbool force=RAbool(false));`

Same as the previous reshape method, but takes an array of new dimensions as an argument. This is the only way to reshape an array of rank twelve or higher.

**Definition:** `void clear();`

This method release memory the memory associated with the rarray. If the rarray was created by providing a pre-existing buffer for the data, the memory of this buffer does not released.

**Definition:** `void fill(const T& value);`

This method fills the array with a uniform value value.

**Definition:** `bool is_clear();`

Checks if the rarray is in an uninitialized state.

**Definition:** `rarray<T,R>& copy() const;`

This method creates deep copy of the rarray, i.e., an independent rarray with the same dimensions are the original rarray and with its content a copy of the original rarray's content.

## 6 Returning a rarray from a function

Unless you're using rarray in a C++11 context, the shallow copying of rarrays causes problems when returning a rarray from a function.

Consider the function zeros used in main():

```
rarray<double,2> zeros(int n, int m) {
    rarray<double,2> r(n,m);
    r.fill(0.0);
    return r;
}
int main() {
    rarray<float,2> s = zeros(100,100);
    return s[99][99];
}
```

In line 2, a rarray 'r' is created, and filled, on line 3, with zeros. On line 4, this array is shallowly copied out of the function and into 's' on line 7. Once copied into 's', 'r' is destroyed and releases its memory, but this leaves 's' in an invalid state (as it points to memory that is no longer allocated).

Instead, we would like the rarray 's' to become responsible for the memory deallocation, i.e., we'd like r to become a shallow copy and s the original. To do so, rarray.h provides the RA\_MOVE macro, which affectively transfers the ownership. In the above example, it should be used as follows:

```
rarray<double,2> zeros(int n, int m) {  
    rarray<double,2> r(n,m);  
    r.fill(0.0);  
    return RA_MOVE(r);  
}
```

In C++11, this kind of behavior can (and will) be implemented using *move semantics*, which make the first form of the `zeros` function work as correctly.

## 7 Conversions

### 7.1 Converting automatic C-style arrays to rarrays

It is possible to convert C-style automatic arrays to rarrays using the `RARRAY` macro (which calls some templated functions under the hood). You can apply `RARRAY` to any automatic array of rank six or less, and even to a rarray (which essentially does nothing). The main convenience of this is that one can write functions that take rarray argument(s) and pass automatic arrays to them. Another use is in initializing a rarray. For example:

```
#include <iostream>  
#include "rarray.h"  
void print2d(const rarray<float,2> &s) {  
    for (int i=0; i<s.extent(0); i++) {  
        for (int j=0; j<s.extent(1); j++)  
            std::cout << s[i][j] << ' ' ;  
        std::cout << std::endl;  
    }  
}  
  
int main() {  
    float printme[4][4] = { { 1.0, 1.2, 1.4, 1.6},  
                           { 2.0, 2.2, 2.4, 2.6},  
                           { 3.0, 3.2, 3.4, 3.6},  
                           { 4.0, 4.2, 4.4, 4.6} };  
  
    print2d(RARRAY(printme));  
    rarray<float,2> a = RARRAY(printme).copy();  
    print2d(a);  
}
```

### 7.2 Conversions for function arguments

A function might take a `rarray<const T,R>` parameter if elements are not changed by it. Because C++ cannot convert a reference to a `rarray<T,R>` to a `rarray<const T,R>`, one has to use the `const_ref` method to do this for you. For example:

```
float add(const rarray<const float,2> &s)  {
    float x = 0.0;
    for (int i=0; i<s.extent(0); i++)
        for (int j=0; j<s.extent(1); j++)
            x += s[i][j];
    return x;
}
int main() {
    rarray<float,2> s(40, 40);
    float z = add(s.const_ref()); // because add() takes <const float>
}
```

rarray objects are also easy to pass to function that do not use rarrays. Because there are, by design, no automatic conversions of a rarray, this is done using methods.

There are two main ways that such functions expect a multidimensional array to be passed: either as a pointer (a T\*) to the first element of the internal buffer composed of all elements, or as a pointer-to-pointer structure (a T\*\*...). In the former case, it may be important to know that a rarray stores elements in row-major format.

With the const keyword, the number of useful C++ forms for multidimensional array arguments has grown to about six. In the case of a two-dimensional array these take the forms: T\*, const T\*, T\*const\*, const T\*const\*, T\*\*, and const T\*\*. Using the rarray library, const-correct argument passing requires the data or ptr\_array method but non-const-correct argument passing will require the noconst\_ptr\_array function, possibly combined with const\_ref. We will briefly looking at these cases separately now.

### 7.3 Conversion to a T\* or a const T\*

A function may expect a multidimensional array to be passed as a simple pointer to the first element, of the form T\*, or of the form const T\*. A rarray object s of type rarray<T,I> can be passed to these functions using the syntax s.data(), which yields a T\*.

#### Example 1:

```
void fill1(float* a, int n1, int n2, float z) {
    for (int i=0; i<n1*n2; i++)
        a[i] = z;
}
int main() {
    rarray<float,2> s(40, 40);
    fill1(s.data(), s.extent(0), s.extent(1), 3.14);
}
```

#### Example 2:

```
float add2(const float* a, int n1, int n2) {
    float x = 0.0;
    for (int i=0; i<n1*n2; i++)
        x += a[i];
    return x;
}
int main() {
    rarray<float,2> s(40, 40);
    float z = add2(s.data(), s.extent(0), s.extent(1));
}
```

C++ accepts a `float*` instead of a `const float*`, so `data()` can be used in the latter example.

#### 7.4 Conversion to a T\*const\* or a const T\*const\*

In `T*const*`, the middle `const` means that one cannot reassign the row pointers. The `rarray` classes can be converted to this type using the `ptr_array()` method. For higher dimensions, this case generalizes to `T*const*const*`, `T*const*const*const*`, etc.

##### Example 1:

```
void fill3(float*const* a, int n1, int n2, float z) {
    for (int i=0; i<n1; i++)
        for (int j=0; j<n2; j++)
            a[i][j] = z;
}
int main() {
    rarray<float,2> s(40, 40);
    fill3(s.ptr_array(), s.extent(0), s.extent(1), 3.14);
}
```

##### Example 2:

```
float add4(const float*const* a, int n1, int n2) {
    float x = 0.0;
    for (int i=0; i<n1; i++)
        for (int j=0; j<n2; j++)
            x += a[i][j];
    return x;
}
int main() {
    rarray<float,2> s(40, 40);
    float z = add4(s.ptr_array(), 40, 40);
}
```

C++ accepts a T\*const\* where a const T\*const\* is expected, so here one can again use the method ptr\_array(). This extends to its generalizations const T\*const\*const\*, const T\*const\*const\*const\*, etc., as well.

## 7.5 Conversion to a T\*\*

Generating a T\*\* from a rarray object, one could change the internal structure of that rarray object through the double pointer. This is therefore considered a not const-correct. It is however commonly needed, so rarray does have a function for it, called noconst\_ptr\_array.

**Example:**

```
void fill5(float** a, int n1, int n2, float z) {
    for (int i=0; i<n1; i++)
        for (int j=0; j<n2; j++)
            a[i][j] = z;
}
int main() {
    rarray<float,2> s(40, 40);
    fill5(s.noconst_ptr_array(), s.extent(0), s.extent(1), 3.14);
}
```

## 7.6 Conversion to a const T\*\*

C++ does not allow conversion from T\*\* to const T\*\*. To convert to a const T\*\*, one first needs to convert the rarray<T,R> to a rarray<const T,R> using const\_ref(), after which one can use the noconst\_ptr\_array function.

**Example:**

```
float add6(const float** a, int n1, int n2) {
    float x = 0.0;
    for (int i=0; i<n1; i++)
        for (int j=0; j<n2; j++)
            x += a[i][j];
    return x;
}
int main() {
    rarray<float,2> s(40, 40);
    float z = add6(s.const_ref().noconst_ptr_array(), 40, 40);
}
```

## 8 Overheads

### 8.1 Memory overhead using the rarray class

The memory overhead here comes from having to store the dimensions and a pointer-to-pointer structure. The latter account for most of the memory overhead. A rarray object of  $100 \times 100 \times 100 \times 100$  doubles on a 64-bit machine will have a memory overhead of a bit over 1%. In general, the memory overhead as a percentage is roughly 100% divided by the last dimension. Therefore, avoid rarrays with a small last dimension such as  $100 \times 100 \times 100 \times 2$ .

### 8.2 Performance overhead using the rarray class

When compiled with optimization on (`-O3 -fstrict-aliasing` is a good default), inlining should make the rarray objects at least as fast as the textbook solution above, for most compilers (tested with gcc 4.6.1 – 4.8.2 and, icc 12.1.5 – 13.1.1 on x86, and with xlC 12.1 on power 6). So in that sense, there is no performance overhead. However, with `RA_BOUNDSCHECK` defined, one incurs a compiler and machine dependent performance hit.

Let us give a bit more details as to why there should not be any performance overhead. Temporary intermediate expression in a multi-bracketed expression (such as `a[5]` in `a[5][6][7]`) are represented by an intermediate class called `rarray_intermediate`. This prevents assignment to such expressions and allows the optional bound checking to work. Most compilers (gcc, intel) can optimize these intermediate classes away when bounds checking is off. However some compilers (e.g. pgi) cannot do this and suffer from speed degradation because of these intermediate objects.

To get full speedup for these less-optimizing compilers, you can define the preprocessor constant `RA_SKIPINTERMEDIATE` (usually with a `-DRA_SKIPINTERMEDIATE` compiler option). Intermediate expression in a multi-bracketed expression are then replaced by bare pointers-to-pointers.

Note that when `RA_BOUNDSCHECK` is set, it will switch off `RA_SKIPINTERMEDIATE`.

### 8.3 Compilation overhead using the rarray class

There is an overhead in the compilation stage, but this is very compiler dependent.
